ANNEX B - TRAFFIC CONTRIBUTION TO AMBIENT CONCENTRATION FIGURES

INTRODUCTION

The Victorian Government is considering how to:

- Best support the development of new vehicle technologies;
- Minimise barriers to efficient implementation and widespread uptake; and
- Ensure the value of the vehicle technologies to the community is maximised.

The population health and environmental impacts are a key contributor to the value that automated vehicles (AV) and zero emission vehicles (ZEV) can deliver to the community. These benefits include the potential for improved air quality and reduced greenhouse gas (GHG) emissions.

Infrastructure Victoria has been directed by the Special Minister to provide advice on the infrastructure required to enable the implementation of AV and ZEV in Victoria. To provide a response to this request for advice, Infrastructure Victoria has developed a number of packages of work. One of the packages considers:

- Potential for improvements in population health (reduced risk of premature mortality and morbidity) due to reduced exposure to pollutants including:
 - Sulphur dioxide (SO₂);
 - Nitrogen dioxide (NO₂);
 - Black carbon (BC);
 - Particulate matter in two size fractions less than 10 µm and 2.5 µm (PM₁₀ and PM_{2.5});
 - Volatile organic compounds (VOCs); and
 - Oxides of carbon including carbon monoxide and carbon dioxide (CO and CO₂).
- How those impacts will vary by socioeconomic and demographic groups across Victoria.

Evaluation of the improvements in population health and variance of impacts across socioeconomic and demographic groups requires data on the road emissions and projected contribution of those emissions to ambient air quality. Environmental Resources Management Australia Pty Ltd (ERM) was engaged by Aurecon Australia Pty Ltd (Aurecon) (the main contract holder with Infrastructure Victoria for this package of work) to undertake air emission estimation for traffic modelling results for Melbourne Metropolitan Area provided to Infrastructure Victoria for the considered scenarios by KPMG.

CONSIDERED SCENARIOS

To provide a response to the request for advice by the Special Minister, Infrastructure Victoria has developed the following scenarios:

- Dead End (base case);
- Slow lane;
- Electric Avenue;
- Fleet street;
- Hydrogen Highway;
- Private Drive; and
- High speed.

Table 2-1 provides a summary of the developed scenarios.

Table 2-1 *Summary of scenarios developed by Infrastructure Victoria*

Scenario	Year	Driving mode	Power Source	Ownership / Market model	Occupancy Level
Dead End	2046	Non-driverless	Petrol/ diesel	Private ownership	Multiple occupancy and single occupancy
Slow Lane	2046	Non-driverless and driverless	Electric and petrol/ diesel	Shared, on-demand services and private ownership	Multiple occupancy and single occupancy
Electric Avenue	2046	Non-driverless	Electric	Private ownership	Single occupancy
Fleet Street	2046	Driverless	Electric	Shared, on-demand services	Multiple occupancy
Hydrogen Highway	2046	Driverless	Hydrogen	Private ownership	Single occupancy
Private Drive	2046	Driverless	Electric	Private ownership	Single occupancy
High speed	2031	Driverless	Electric	Shared, on-demand services	Multiple occupancy

All scenarios, except for High Speed, have been run by KPMG to produce detailed traffic modelling statistics and link by link data. The link by link data was then provided to ERM to enable air emission estimation.

No detailed traffic modelling statistics or link by link data have been produced by KPMG for the High Speed scenario. Summary statistics for this scenario was derived by KPMG by interpolation of 2046 model runs. The summary statistics did not contain sufficient detail for air emission estimation and therefore this scenario has been excluded from further consideration in this assessment.

Moreover, traffic modelling results produced by KPMG included both Private Drive and Private Drive Empty Running scenarios. ERM was instructed by

Infrastructure Victoria to consider both of these scenarios within the air emission estimation (email dated 16 May 2018). ERM understands that the Private Drive Empty Running scenario considered the return of empty vehicles back to their base after dropping the passenger off, whilst the Private Drive scenario did not consider these additional empty vehicle movements. ERM therefore understands that Private Drive Empty Running scenario is in fact a correction of Private Drive scenario. This assessment however considered both Private Drive and Private Drive Empty Running scenarios as instructed on 16 May 2018.

Table 2-2 provides the summary of scenarios considered in this assessment.

Table 2-2 *Summary of scenarios considered in this assessment*

Scenario	Driving mode	Power Source	Ownership / Market model	Occupancy Level
Dead End	Non-driverless	Petrol/diesel	Shared, on-demand services and private ownership	Multiple occupancy and single occupancy
Slow Lane	Non-driverless and driverless	Electric and petrol/diesel	Shared, on-demand services and private ownership	Multiple occupancy and single occupancy
Electric Avenue	Non-driverless	Electric	Private ownership	Single occupancy
Private Drive	Driverless	Electric	Private ownership	Single occupancy
Private Drive Empty Running	Driverless	Electric	Private ownership but vehicles return to base empty	Single occupancy
Fleet Street	Driverless	Electric	Shared, on-demand services	Multiple occupancy
Hydrogen Highway	Driverless	Hydrogen	Private ownership	Single occupancy

The Dead End scenario forms the base case as this assumes that the move to AV / ZEV does not occur and that improvements in combustion engine technology continue to the assessment year. The Dead End scenario therefore forms the closest approximation of the current use of vehicles within the assessment year. Changes resulting from the other scenarios are therefore made in comparison to Dead End.

It should be also noted that at the time of emission estimation, ERM was only provided with the spatial information for Melbourne metropolitan road links and therefore emission estimation has been limited to Melbourne metropolitan areas.

The extent of the data provided by KPMG did not include current traffic flows, consequently it was not possible to provide a direct comparison of the estimated emissions for the Dead End scenario to current impact.

EMISSION ESTIMATION

ERM was provided with traffic statistics for each road link (local, arterial and freeway) for the scenarios described in *Table 2-1*.

Emission estimation for each scenario was undertaken using the following excel workbooks provided to ERM by Infrastructure Victoria:

- IV AZEVIA Dashboard 20180515 PRELIMINARY DRAFT v8.xlsb; and
- Metro Melb modelling = link_stats_20180504.

Dead End and Slow Lane scenario projections for 2046 included traditional fleet, which comprised combustion vehicles. Emissions from these scenarios therefore comprised both exhaust and non-exhaust emissions.

Electric Avenue, Fleet Street, Private Drive and Private Drive Empty Running scenario projections for 2046 included electric vehicles only, some of which are automated (robotaxi). Emissions from these scenarios therefore comprised only non-exhaust emissions.

Hydrogen Highway scenario projection for 2046 included hydrogen vehicles only. Hydrogen vehicles are associated with the following emissions:

- Non-exhaust; and
- Water vapour.

Water vapour is not directly linked to human health impacts, as such emission estimation for this scenario only considered non-exhaust emissions.

3.1

EXHAUST EMISSIONS

Exhaust emissions for all scenarios were calculated using COPERT Australia software. *COPERT Australia* is a MS Windows software, designed by EMISIA SA (a spin-off company of the Aristotle University of Thessaloniki) and the Queensland Department of Science, Information Technology, Innovation and the Arts, to calculate air emissions from road transport in Australia. The COPERT Australia model's algorithms were developed from data collected in Australian test programs designed to reflect the Australian fleet and activity data (EMISIA SA, 2014). The *COPERT Australia* model accounts for various types of emissions including hot running, cold-start and evaporative emissions and covers 226 different vehicles classes and 116 species.

In order to calculate emissions, COPERT Australia software requires the following inputs:

- Region and fuel information;

- Fleet configuration; and
- Activity data.

3.1.1 *Region and Fuel Information*

Table 3-1 provides region information used in all *COPERT Australia* software runs. Table 3-2 and Table 3-3 provide fuel information used in all *COPERT Australia* software runs. It should be noted that all the scenarios adopted default fuel information contained in *COPERT Australia* database, unless alternative information was available.

Table 3-1 *Region Information adopted in COPERT Australia software runs*

3.1.2 Fleet Configuration

All of the scenarios considered in this assessment (Table 2-2) contain traffic projections for year 2046. It was considered that by 2046 the traditional fleet will undergo a number of fleet replacements and therefore is likely to comprise the vehicles at a minimum containing the best available current engine and emissions control technology. Table 3-4 provides the technology for each vehicle class adopted in all *COPERT Australia* software runs. It should be noted that, whilst public transport and motorcycle data was provided on a regional basis, the methodology adopted required detailed information on a road link basis. As public transport and motorcycle data was not available for individual road links, emissions from these vehicle classes could not be estimated within the adopted approach. It is considered that contributions from these vehicle classes would not be significant, and therefore not including these vehicle classes would not result in a significant under-estimation of contribution to ambient air quality from road sources within the considered scenarios.

Table 3-4 Vehicle technologies adopted in COPERT Australia model

Sector	Subsector	Technology
Passenger Cars	PC-S-petrol	ADR79-05

Heavy Duty Trucks	AT-diesel	ADR80-05
Heavy Duty Trucks	Autogas Trucks	ADR80-05

3.1.3 Activity Data

Activity data inputs within *COPERT Australia* software runs require the following information for each vehicle technology class:

- Input fleet data:

- Population (number of vehicles);
- Mileage (km/year); and
- Mean fleet mileage (km);
- Input Circulation Data:
 - Speed (km/hr) on each type of road (urban, rural, highway); and
 - Driving share (percentage) for each type of road (urban, rural, highway); and
- Input Evaporation Data.

Given the number of road links included in each scenario, rather than use COPERT to model every link within the dataset, COPERT was used to estimate emissions on a nominal number of vehicles (1,000,000 vehicles) and a 1 km per year mileage basis and use the calculated emission rates to scale the emissions for each road link in Excel spreadsheet. This approach using emission factors in spreadsheets is an industry standard which has been used on road projects throughout Australia. All scenarios adopted default mean fleet mileage¹ contained in the COPERT Australia software.

Within the provided traffic movement dataset, there are three different types of roads (local, arterial and freeways). Each road type is allocated, within the provided KPMG dataset, with a specific average speed under each scenario. ERM therefore used the COPERT Australia model to develop three runs for each scenario, each specific to each road type and the associated average speed. *Table 3-5* provides input circulation data parameters for each run undertaken for Dead End scenario and *Table 3-6* provides input circulation data parameters for each run undertaken for Slow Lane scenario. It should be noted that passenger cars (PCs), SUVs and light commercial vehicles (LCVs) adopted speeds provided for private vehicles, while heavy duty trucks (HDT) adopted speeds provided for freight. It should be noted that COPERT was not used for the remaining five scenarios as there are no tailpipe emissions from ZEV.

¹ The mean fleet mileage describes the number of kilometres that each vehicle class has typically travelled thus describing the age of the vehicle fleet, and any deterioration in engines and mitigation technology since introduction of the vehicle to the fleet.

Table 3-5 *Circulation data parameters adopted for each Dead End COPERT Australia run*

Sector	Speed (km/hr)	Driving share
Local roads run		
PC ¹ , SUV and LCV ²	29.5	Urban 100%
HDT ³	34.2	Urban 100%
Arterial roads run		
PC, SUV and LCV	32.5	Urban 100%
HDT	33.2	Urban 100%
Freeways roads run		
PC, SUV and LCV	56.1	Highway 100%
HDT	58.2	Highway 100%
1. PC stands for passenger cars of all classes 2. LCV stands for light commercial vehicle 3. HDT stands for heavy duty truck		

Table 3-6 *Circulation data parameters adopted for each Slow Lane COPERT Australia run*

Sector	Speed (km/hr)	Driving share
Local roads run		
PC ¹ , SUV and LCV ²	36	Urban 100%
HDT ³	41	Urban 100%
Arterial roads run		
PC, SUV and LCV	46	Urban 100%
HDT	44	Urban 100%
Freeways roads run		
PC, SUV and LCV	78	Highway 100%
HDT	81	Highway 100%
1. PC stands for passenger cars of all classes 2. LCV stands for light commercial vehicle 3. HDT stands for heavy duty truck		

It should be noted that no evaporative emissions were considered in this assessment for any scenario. COPERT Australia runs were calculated on a road link by road link basis, while evaporative emissions are not necessarily linked to traffic on the roads as they include:

- Diurnal emissions due to thermal expansion and emission of vapour from the fuel tank of stationary vehicle due to diurnal changes in ambient temperature;
- Hot soak losses – emissions from a warmed-up vehicle after the vehicle and engine stopped;
- Evaporative emissions during idling; and
- Refuelling losses.

It was therefore considered incorrect to include evaporative emissions in this assessment.

Air emission Inventory for the Greater Metropolitan Region in New South Wales projection data for Sydney, derived from 2008 data, suggests that in 2016 the evaporative emissions contributed approximately 59 percent of total vehicle-related VOCs emissions. It is therefore considered that a similar magnitude of change would be expected for total VOCs emissions in Melbourne metropolitan area.

Table 3-7 Breakdown of total vehicle-related VOCs emissions for Sydney

Source of VOCs emissions	Emissions (tonnes/year)	Percent of total (%)
Evaporative (all)	10,057	59
Non-exhaust (all)	0	0
Heavy Duty Vehicles exhaust	320	2
Light Duty Vehicles (LDV) petrol exhaust	1,586	9
LDV diesel exhaust	200	1
Other exhaust	243	1
Car petrol exhaust	4,629	27
Grand Total	17,035	100

1. (New South Wales Environment Protection Authority, 2008)

3.1.4 COPERT Australia Outputs for non-BTEX Species

Table 3-7, Table 3-8 and Table 3-9 provide air emissions in tonnes per year estimated using COPERT Australia for each vehicle technology class for local, arterial and freeway road runs respectively for Dead End and Slow Lane scenarios for the following species:

- Carbon Monoxide (CO);
- Volatile Organic Compounds (VOCs);
- Nitrogen oxides (NO_x);
- Particulate matter of aerodynamic diameter of 2.5 microns (PM_{2.5});
- Particulate matter of aerodynamic diameter of 10 microns (PM₁₀); and
- Sulphur dioxide (SO₂).

As previously discussed, the air emissions in tonnes per year provided in Table 3-7, Table 3-8 and Table 3-9 are based on 1,000,000 vehicles in each vehicle technology class and a 1 km per year mileage. The estimates were also based on the vehicle speeds provided in IV AZEVIA Dashboard 20180515 PRELIMINARY DRAFT v8.xlsx spreadsheet (Table 3-5 and Table 3-6).

Table 3-8 COPERT Australia outputs for Dead End Scenario Local Roads Run

3.1.5

COPERT Setup for BTEX Emissions

Unlike other species, non-methane VOCs (NMVOCs) speciation in COPERT Australia output is provided per fleet rather than for each vehicle technology class. Additional runs were therefore undertaken to derive emissions for benzene, toluene, ethylbenzene and xylenes (BTEX) for cars and trucks separately to match the traffic data provided to ERM. In order to simplify calculations within Excel, these runs were based on a fleet of a nominal number of 1,000,000 vehicles with a Melbourne traffic make up (Pacific Environment Limited, 2016) as provided in *Table 3-10* for car run and *Table 3-11* for truck run. Six BTEX species runs for each scenario were therefore undertaken:

- Car and Truck runs for local roads;
- Car and Truck runs for arterial roads; and
- Car and Truck runs for freeways.

Input circulation data for each road type remained consistent with the parameters used for emission estimation for other species (*Table 3-5* and *Table 3-6*).

3.1.7 Emission Estimation per Road Link

Air emissions in tonnes per year based on mileage of 1 kilometre per year were then used to calculate average emissions in grams per hour per kilometre for each road link using Equation 3-1 for both non-BTEX species and BTEX species. For non-BTEX species this equation is based on vehicle technology classes, while for BTEX species this equation is based on broader categories: cars and trucks. It should be noted that mileage of 1 kilometre per year basis was adopted to simplify excel spreadsheet calculations.

Equation 3-1 Emission estimation per road link for non-BTEX species

$$RLE_i = \sum_j \frac{N_j}{1,000,000} \times E_{ij}$$

Where

- RLE_i is road link emission for species i in g/hr/km
- N_j is average number of vehicles in class j in a year for non-BTEX emissions and average number of cars/trucks in a year for BTEX emissions
- E_{ij} is emission rate for species i for vehicle class j in tonnes/year/km/million vehicles for non-BTEX emissions and emission rate for cars/trucks in tonnes/year/km/million vehicles for BTEX emissions

3.2 NON-EXHAUST EMISSIONS PER ROAD LINK

Non-exhaust emissions from vehicles comprise airborne particles produced as a result of the interaction between a vehicle's tyres and the road, including when the brakes are applied to decelerate the vehicle (European Environment Agency, 2016). These emissions are known as:

- Tyre wear;
- Brake wear; and
- Road surface wear.

Resuspension particulate matter is also a non-exhaust emission source, which relates to both freshly formed particles from abrasion and older deposited road dust brought into the air by vehicle movement (Martin Ferm, 2015). There is however an ongoing discussion on whether this source can be considered a primary source and the uncertainty in the methods for the estimation of emission factors (European Environment Agency, 2016).

3.2.1 *Combustion Vehicles*

COPERT Australia was used to only calculate exhaust emissions. Non-exhaust emissions for combustion vehicles for Dead End and Slow Lane scenarios were calculated in accordance with EMEP/EEA Air Pollutant Emission Inventory Guidebook 2016 (European Environment Agency, 2016). Emissions for tyre, brake and road surface wear for heavy duty vehicles was undertaken using Tier 1 methodology as no information was provided on the fleet split based on the number of truck axles (which is required for a Tier 2 assessment). Emissions for tyre, brake and road surface wear for passenger cars and light-duty vehicles however was based on Tier 2 methodology and accounted for different road speeds. Non-exhaust PM_{2.5} and PM₁₀ emissions were estimated for each road link using the fleet numbers provided for each scenario. Non-exhaust emissions per road link in g/hr/km were then added to exhaust emissions for the same road link.

3.2.2 *Electric and Hydrogen Vehicles*

A literature review was completed to compare non-exhaust emissions from combustion and electric vehicles. At the current time there is little available literature on non-exhaust PM emissions from electric vehicles, however one published study drew the following comparative conclusions (Victor R.J.H. Timmers, 2016):

- Tyre wear emissions of PM₁₀ and PM_{2.5} from electric vehicles are slightly higher than gasoline and diesel combustion vehicles:
 - 7.2 mg/vkm for electric vehicles compared to 6.1 mg/vkm for combustion vehicles of PM₁₀; and
 - 3.7 mg/vkm for electric vehicles compared to 2.9 mg/vkm for combustion vehicles of PM_{2.5};

- Brake wear emissions of PM₁₀ and PM_{2.5} from electric vehicles are significantly lower than gasoline and diesel combustion vehicles due to regenerative brake system:
 - 0 mg/vkm for electric vehicles compared to 9.3 mg/vkm for combustion vehicles of PM₁₀;
 - 0 mg/vkm for electric vehicles compared to 2.2 mg/vkm for combustion vehicles of PM_{2.5};
 - It should be noted that zero brake wear emissions from electric vehicles have been conservatively adopted by the study due to limited research of this emission source (Victor R.J.H. Timmers, 2016).
- Road wear emissions of PM₁₀ and PM_{2.5} from electric vehicles are slightly higher than gasoline and diesel combustion vehicles due to heavier weight of the electric vehicles due to heavy batteries:
 - 8.9 mg/vkm for electric vehicles compared to 7.5 mg/vkm for combustion vehicles of PM₁₀; and
 - 3.8 mg/vkm for electric vehicles compared to 3.1 mg/vkm for combustion vehicles of PM_{2.5};
- Resuspension emissions of PM₁₀ and PM_{2.5} from electric vehicles are higher than gasoline and diesel combustion vehicles:
 - 49.6 mg/vkm for electric vehicles compared to 40 mg/vkm for combustion vehicles of PM₁₀; and
 - 14.9 mg/vkm for electric vehicles compared to 12 mg/vkm for combustion vehicles of PM_{2.5}.

Overall, the research paper (Victor R.J.H. Timmers, 2016) indicates that electric vehicles are associated with non-exhaust emissions of 65.7 mg/vkm of PM₁₀ and 22.4 mg/vkm of PM_{2.5}, compared to 62.9 mg/vkm and 20.2 mg/vkm associated with gasoline and diesel vehicles.

While the research paper by Victor R.J.H. Timmers and A.J. Achten indicates that the total non-exhaust emissions from electric vehicles are 4.5 % higher for PM₁₀ and 11% higher for PM_{2.5}, these total emission estimates take into account resuspension emissions (Victor R.J.H. Timmers, 2016). As previously discussed however, there is limited research on this emission source and the uncertainties surrounding the methods for the estimation of emission factors (European Environment Agency, 2016). There is an ongoing discussion on whether this source can be considered primary and therefore there is potential for double-counting of emissions (Victor R.J.H. Timmers, 2016). For these reasons EMEP/EEA Air Pollutant Emission Inventory Guidebook 2016 (European Environment Agency, 2016) does not contain emission factors for resuspension and therefore these emission rates were not included in the assessment.

If resuspension emission rates are ignored in comparative analysis between electric and combustion vehicles, non-exhaust emissions from electric vehicles are significantly reduced compared to combustion vehicles. In order not to overstate health benefits from adoption of electric vehicles in this assessment, this assessment conservatively adopted the same non-exhaust emission factors for electric vehicles as for combustion vehicles. Non-exhaust emissions for electric and hydrogen vehicles for Electric Avenue, Fleet Street, Private Drive, Private Drive Empty Running and Hydrogen Highway scenarios therefore were estimated using the same approach as described in *Section 3.2.1*. It is recommended that non-exhaust emission factors for electric and hydrogen vehicles adopted in this assessment are revisited once the research is more conclusive about the total non-exhaust emission rates associated with these types of vehicles.

3.3 TOTAL EMISSION REDUCTIONS

The health impact assessment, to which this report is appended, required detail on total emission reduction for each SA2 region for each considered species. In order to estimate total emission reductions from scenarios as compared to base case (Dead End scenario), total emissions in kilograms per year for each species (from both exhaust and non-exhaust emissions) were first calculated for each road link using *Equation 3-2*. Total emissions for each road link were then added for each SA2 region to estimate total emission reduction per SA2 region.

Equation 3-2 Total emission in kilograms per year estimated for each road link

$$TE_i = \frac{RLE_i \times 365 \times 24 \times L}{1,000}$$

Where

TE_j is total emission for species i in kg/year

RLE_i is total road link emission for species i in g/hr/km (including exhaust and non-exhaust emissions)

L is road length in km

3.4 GREENHOUSE GAS EMISSIONS

Greenhouse gas emissions for the Dead End and Slow Lane scenarios were estimated using the *Road Transport Emission Factors: 2010 NAEI* (NAEI, 2012). These emission factors are based on the analysis of emission test data for in-service vehicles in the UK for a range of drive cycles. There are emission factors based on vehicle type, fuel used and mode of transport.

The emission factors are reported in mass per km travelled and include the greenhouse gases carbon dioxide (CO₂) and nitrous oxide (N₂O). A CO₂

equivalence (CO_{2e}) emission factor was determined by multiplying the N₂O emissions factor to its global warming potential (298) and adding it to the CO₂ emission factor. The resulting emission factors were applied to the same data used in the COPERT modelling. Based on the reported vehicle type the relevant CO_{2e} was applied for the assumed road lengths travelled on the different road types. The resulting estimated annual greenhouse gas emissions are:

- Dead End Scenario - 22,855,000 tonnes of CO_{2e} / year
- Slow Lane Scenario - 17,424,000 tonnes of CO_{2e} / year

As greenhouse gases do not directly impact population health, no further assessment has been completed.

In relation to concentrations of NO₂ and PM_{2.5}, the health risk assessment required additional detail in relation to exposure for each SA2 region. To provide this information to the health risk assessment, emission estimation results for each scenario for NO₂ and PM_{2.5}, completed using the methodology outlined in Section 3, were used to assess population exposure to traffic pollution. This part of the assessment was performed using the geographic information system ArcGIS, adopting the following inputs:

- 2046 road network shapefile provided to ERM by Infrastructure Victoria;
- Total emissions per road link for each scenario calculated using methodology outlined in *Section 3*;
- Statistical Area Level 2 (SA2) Edition 2016 Digital Boundaries in ESRI Shapefile Format (Australian Bureau of Statistics, 2017); and
- Population for Victoria on square kilometre basis as collected by Australian Bureau of Statistics (ABS) based on 2016 census, provided to ERM.

It should be noted that 2046 population statistics, developed as part of the wider study, were available only at the level of SA2 areas and therefore did not provide sufficient detail on how the population is likely to locate spatially within SA2 areas in relation to the location of the road network. This assessment therefore used population distribution on one square kilometre basis, available from ABS for year 2016. This allowed the analysis to identify the areas with population exposed to traffic pollution within SA2 regions. ERM understands that the analysis results provided to Aurecon for health impacts assessment were then scaled to reflect the likely population growth by 2046.

The population exposure to traffic pollution for each scenario was derived through the following steps:

- Buffers of 2, 5, 10, 25, 50, 100, 150, 168, 175, 200 metres were created around each road link;
- Point data set created for each road buffer using 'Features Vertices to Points' tool;
- Annual mean contribution to ambient air quality in µg/m³ from each road link was calculated for each buffer area using equations provided in Section C3.2 of Design Manual for Roads and Bridges (The Highways Agency, Transport Scotland, Welsh Assembly Government Llywodraeth Cynulliad Cymru, the Department for Regional Development Northern Ireland, 2007);
- Point data was interpolated using inverse distance weighted interpolation method (IDW tool);
- Grids were summed for each road link using cell statistics tool;

- Traffic contribution grids were summed for all road links for each scenario to derive final contribution grids;
- A fishnet was created with a cell size of 1 km² using the extent contained in the population data;
- Population raster values for each fishnet cell were derived using spatial join with data derived from the Australian Bureau of Statistics for population data based on the 2016 census²; and
- The average concentration for each cell (square kilometre) of population statistics was derived using zonal statistics tool.

The average concentration for each square kilometre of population statistics data for all SA2 regions was provided to Aurecon in spreadsheet form to assist the health risk assessment of NO₂ and PM_{2.5} emissions.

5.1 EMISSION REDUCTIONS

Total NO_x, CO, VOCs, PM_{2.5}, PM₁₀, SO₂, benzene, toluene, ethylbenzene and xylenes emissions in kilograms per year for all scenarios are provided in Annex A. Dead End scenario has been adopted as a base case in this assessment and all other scenarios have been compared to the base case emissions.

The results of the emission estimation indicate that overall, for Melbourne Metropolitan area, all scenarios achieve reduction in emissions of all species, as compared to the base case. *Table 5-1* presents the total emission reduction (percent) for all species for Melbourne Metropolitan area for all scenarios considered in this assessment in comparison to the base case (Dead End scenario).

Table 5-1 Total emission reduction (percent) for all scenarios in comparison to the base case for Melbourne Metropolitan area

Species	Total emission reduction (%)					
	Slow Lane	Electric Avenue	Hydrogen Highway	Private Drive	Private Drive Empty Running	Fleet Street
CO	51	100	100	100	100	100
VOCs	51	100	100	100	100	100
NOX	30	100	100	100	100	100
PM _{2.5}	18	44	41	40	36	48
PM ₁₀	17	43	41	40	36	48
SO ₂	42	100	100	100	100	100
Benzene	81	100	100	100	100	100
Toluene	82	100	100	100	100	100
Ethylbenzene	82	100	100	100	100	100
Xylenes	76	100	100	100	100	100

The emission estimation results presented in *Table 5-1* indicate that Electric Avenue, Hydrogen Highway, Private Drive, Private Drive Empty Running and Fleet Street achieve 100 percent reduction in the annual emissions of CO, VOCs, NO_x, SO₂, Benzene, Toluene, Ethylbenzene and Xylenes in Melbourne Metropolitan area compared to the base case. These emission reductions are due to traffic in these scenarios comprising only electric or hydrogen vehicles, which are not associated with hydrocarbon combustion exhaust emissions. These scenarios are also associated with the overall reduction in PM₁₀ and PM_{2.5} emissions as compared to the base case, which are also attributed to the elimination of particulate matter emissions from the exhausts.

The emission estimation results presented in *Table 5-1* further indicate that Slow Lane scenario achieves overall reduction in the annual emissions of all species in Melbourne Metropolitan area, as compared to the base case. These overall reduction is associated to the traffic in Slow Lane being split between combustion vehicles and electric vehicles, therefore reducing overall exhaust emissions.

On an individual SA2 level, the results of the emission estimation indicate that Electric Avenue, Hydrogen Highway, Private Drive and Fleet Street scenarios achieve emission reductions in emissions of all species for all SA2 regions compared to the base case. *Table 5-2* shows minimum and maximum reductions in PM_{2.5} and PM₁₀ emissions for individual SA2 areas for Electric Avenue, Hydrogen Highway, Private Drive and Fleet Street scenarios compared to the base case.

Table 5-2 *Minimum and Maximum reductions in Pm2.5 and PM10 emissions for SA2 areas within Melbourne Metropolitan area for Electric Avenue, Hydrogen Highway, Private Drive and Fleet Street compared to the base case*

Scenario	PM _{2.5}		PM ₁₀	
	Minimum reduction	Maximum reduction	Minimum reduction	Maximum reduction
	(%)	(%)	(%)	(%)
Electric Avenue	40	49	39	49
Hydrogen Highway	8	56	7	56
Private Drive	11	57	10	56
Fleet Street	25	73	25	73

On individual SA2 level, the results of the emission estimation indicate that Private Drive Empty Running and Slow Lane scenarios achieve emission reductions in PM_{2.5} and PM₁₀ emissions for the majority of SA2 regions, however an increase in PM_{2.5} and PM₁₀ emissions is projected for a number of SA2 regions.

Table 5-3 and *Table 5-4* present the SA2 areas associated with the increase in particulate matter emission in the Private Drive Empty Running and Slow Lane scenarios respectively compared to the base case and the magnitude of change in kilograms per year. The increases in particle emissions for each SA2 region presented in *Table 5-3* and *Table 5-4* are associated with the overall increase in vehicle numbers on roads within these SA2 regions as provided in the results of the traffic modelling. Even though electric vehicles are not associated with exhaust particulate matter emissions, the increase in vehicle kilometres travelled within the Private Drive Empty Running and Slow Lane scenarios and associated non-exhaust particulate matter emissions outweigh elimination of exhaust particulate matter emissions.

It should be also noted that Slow Lane scenario is associated with the overall increase in both car and truck numbers, while in Private Drive Empty Running

scenario there is a negative change in total truck numbers, however this negative change is not as substantial as the increase in cars numbers.

Table 5-3 *Increase in particulate matter emissions (kilograms per year) in Private Drive Empty Running scenario compared to the base case*

SA2 REGION	Reporting region ¹	Increase in emissions (kg/year)	
		PM _{2.5}	PM ₁₀
Carlton		208.2	444.6
Fitzroy		78.6	173.8
Melbourne	Inner Metro	1409.5	2724.9
South Yarra - West		256.8	509.6
St Kilda		130.6	267.4
St Kilda East		61.4	150.2

1. As provided to ERM in Master Network Nodes shapefile

Table 5-4 *Increase in particulate matter emissions (kilograms per year) in Slow Lane scenario compared to the base case*

SA2 REGION	Reporting region ¹	Increase in emissions (kg/year)	
		PM _{2.5}	PM ₁₀
Albert Park	Inner Metro	70.3	339.3
Melbourne	Inner Metro	309.3	627.7
Seabrook	Mid-Western	15.6	43.0
South Melbourne	Inner Metro	286.9	527.6
South Yarra - West	Inner Metro	7.1	91.5
St Kilda	Inner Metro	0.4	172.3
St Kilda East	Inner Metro	103.3	284.1

1. As provided to ERM in Master Network Nodes shapefile

The minimum and maximum reductions in PM_{2.5} emissions for other SA2 areas for Private Drive Empty Running scenario as compared to the base case are from 2 to 56 percent respectively; and the minimum and maximum reductions in PM₁₀ emissions for other SA2 areas for this scenario compared to the base case are from 0 to 56 percent respectively. The minimum and maximum reductions in PM_{2.5} emissions for other SA2 areas for Slow Lane scenario as compared to the base case are from 0 to 36 percent respectively; and the minimum and maximum reductions in PM₁₀ emissions for other SA2 areas for this scenario compared to the base case are from 0 to 35 percent respectively.

As previously discussed, in relation to concentrations of NO₂ and PM_{2.5}, the health risk assessment required additional detail in relation to exposure for each SA2 region. This information has been prepared using ArcGIS software.

Figure 5-1 to Figure 5-9 show traffic contribution to annual mean ambient concentration of PM_{2.5} for each scenario and annual mean NO_x for Dead End and Slow Lane scenarios. *Figure 5-1* and *Figure 5-3* demonstrate that annual mean NO_x concentrations along major freeways are reduced in the Slow Lane scenario compared to the base case. *Figure 5-2* and *Figure 5-4* to *Figure 5-9* demonstrate that annual mean PM_{2.5} concentrations along the majority of freeways and arterial roads are reduced in all scenarios compared to the Dead End scenario (base case). *Figure 5-2* further indicates that Dead End scenario PM_{2.5} contribution is relatively high around all metropolitan areas, while PM_{2.5} contributions for all other scenarios are concentrated around the major freeways in a close proximity to the Melbourne Central Business District (CBD).

CONCLUSION

Infrastructure Victoria has been directed by the Special Minister to provide advice in relation to the impact of AV and ZEV to the Victorian economy, which includes a response on potential for improvements in population health (reduced risk of premature mortality and morbidity) due to reduced exposure to a number of pollutants and how those impacts will vary by socioeconomic and demographic groups across Victoria. ERM was engaged by Aurecon (the main contract holder with Infrastructure Victoria for this package of work) to undertake air emission estimation for traffic modelling results for Melbourne Metropolitan Area provided to Infrastructure Victoria for the considered scenarios by KPMG.

The scope of work included seven scenarios for which traffic projections for the assessment year of 2046 as provided to ERM:

- Dead End (base case);
- Electric Avenue;
- Fleet street;
- Hydrogen Highway;
- Private Drive;
- Private Drive Empty Running; and
- Slow lane.

Dead End and Slow Lane scenario projections for 2046 included the traditional fleet, which comprised combustion vehicles. Emissions from these scenarios therefore comprised both exhaust and non-exhaust emissions. Electric Avenue, Fleet Street, Private Drive and Private Drive Empty Running scenario projections for 2046 included electric vehicles only, some of which are automated (robotaxi). Emissions from these scenarios therefore comprised only non-exhaust emissions. Hydrogen Highway scenario projection for 2046 included hydrogen vehicles only and therefore emissions from this scenario comprised only non-exhaust emissions.

Exhaust emissions for all scenarios were calculated using COPERT Australia software (EMISIA SA, 2014). Non-exhaust emissions for all scenarios were calculated in accordance with EMEP/EEA Air Pollutant Emission Inventory Guidebook 2016 (European Environment Agency, 2016). The estimated emissions were then used to calculate total emission reductions per SA2 region for each species for each scenario as compared to the base case (Dead End) scenario.

The results of the emission estimation indicate that overall, for Melbourne Metropolitan area, all scenarios achieve reduction in emissions of all species, as

compared to the base case. Furthermore, Slow Lane scenario achieves emission reduction for each SA2 region for combustion related emissions (CO, NO_x, VOCs, SO₂, benzene, toluene, ethylbenzene and xylenes) compared to the base case (Dead End scenario). All other scenarios achieve 100% total emission reductions per SA2 region for these species as these species are not emitted from electric or hydrogen vehicles.

The results of the emission estimation further indicate that Electric Avenue, Hydrogen Highway, Private Drive and Fleet Street scenarios achieve emission reductions in PM_{2.5} and PM₁₀ emissions for all SA2 regions individually compared to the base case. For Private Drive Empty Running and Slow Lane scenarios, emission reductions in PM_{2.5} and PM₁₀ emissions are achieved for the majority of SA2 regions, however an increase in PM_{2.5} and PM₁₀ emissions is projected for a number of SA2 regions.

The increase in particle emissions for some SA2 regions in Private Drive Empty Running scenario compared to the base case is associated with the overall increase in car numbers on roads within these SA2 regions as provided in the results of the traffic modelling. The increase in particle emissions for some SA2 regions in Slow Lane scenario compared to the base case is associated with the overall increase in both car and truck numbers on roads within these SA2 regions as provided in the results of the traffic modelling. Therefore for these scenarios even though electric vehicles are not associated with the exhaust particulate matter emissions, the increase in vehicle kilometres travelled within scenario and associated non-exhaust particulate matter emissions outweigh elimination of exhaust particulate matter emissions.

In relation to concentrations of NO₂ and PM_{2.5}, the health risk assessment required additional detail in relation to exposure for each SA2 region and therefore additional analysis was undertaken using the geographic information system ArcGIS to provide this information to the health risk assessment. The results of the analysis indicate that annual mean NO_x concentrations along major freeways are visibly reduced in Slow Lane scenario compared to the base case and annual mean PM_{2.5} concentrations along the majority of freeways and arterial roads are visibly reduced in all scenarios compared to the base case. The analysis further indicates that Dead End scenario PM_{2.5} contribution is relatively high around all metropolitan areas, while PM_{2.5} contributions for all other scenarios are concentrated around the major freeways in a close proximity to the Melbourne Central Business District (CBD).
